Fire risk report for *Neolitsea cassia*

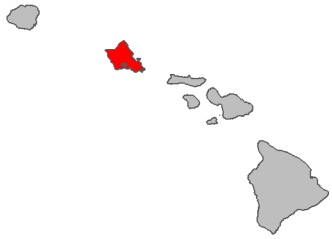
Full Species Name
Neolitsea cassia (L.) Kosterm.

Family: Lauraceae

Common names:

Synonyms:
Cinnamomum cassia
Cinnamomum aromaticum

Known occurrences (as of 2020)



Year first documented as naturalized in Hawai'i: 2015

This species has not yet been ranked by the Hawai'i Weed Risk Assessment program as of 2020.

0	.5	1
Lowest risk	⇔	Highest risk

This species is likely a **low** fire risk in Hawai'i with a fire risk score of **0.22**.

This species was ranked by our machine learning algorithm using the data presented on the next page. A predicted score of > .34 suggests the plant is a high fire risk.

Summary of Fire ecology	
Native habitat fire proneness	Non Fire-prone
Fire promoting plant in its native range	No
Fire promoting plant in its introduced range*	No
Regenerates after fire	No Data
Promoted by fire	No
Reported flammable*	No Data
Relative is flammable*	Yes

*These values were used by the model to predict fire risk

Detailed summary of Fire Ecology

Native habitat fire proneness (In any part of the plant's native range is its habitat described as fire prone due to natural or human caused fires?)	Non Fire-prone	" The shola forest harbors many endemic and rare plant species that cannot regenerate in grasslands and exposed sites due to lack of tolerance to fire and frost (Meher-Homji 1967). [appendix 1 lists that this community contains C. cassia]" Davidar, P., Dass, D. M., & Vijayan, S. L. (2007). Floristic inventory of woody plants in a tropical montane (shola) forest in the Palni hills of the Western Ghats, India. Tropical Ecology, 48(1), 15-26.
Fire promoting plant in its native range (Does the species act as a major fuel source, increase fire severity, frequency, or modify fuel bed characteristics within its native range?)	No	"[appendix 1 lists C. cassia only in unburned plots]" #, this was an observational study, so it may never have been in the burned communities https://doi.org/10.1016/j.foreco.2006.01.016 Shibayama, T., Ashton, M. S., Singhakumara, B., Griscom, H. P., Ediriweera, S., & Griscom, B. W. (2006). Effects of fire on the recruitment of rain forest vegetation beneath Pinus caribaea plantations, Sri Lanka. Forest ecology and management, 226(1-3), 357-363.
Fire promoting plant in its introduced range (Same as Fire Promoting Native but within the species introduced range)	No	No Data
Regenerates after fire (Does the plant regrow after fire by any means? This includes resprouters, reseeders, and recruiters which dispersed into the area within approximately one year post fire)	No Data	
Promoted by fire (Does the plant increase in abundance after a fire?)	No	
Reported flammable (Is the species described as being flammable,	No Data	

being a major wildfire fuel, or high fire risk?)		
Relative is flammable (Does a plant in the same genus meet the Reported Flammable criteria?)	Yes	"Results showed that the eight species could be grouped into two categories: the first one included Camellia oleifera and Cinnamomum camphora, which were highly ignitable but low combustible and sustainable," Jin S, Wang SR. [Evaluation of three-dimensional flammability of eight forest fuels based on thermogravimetric analysis in Nanchang region, China]. Ying Yong Sheng tai xue bao = The Journal of Applied Ecology. 2015 Dec;26(12):3657-3662.

The data presented were assembled from literature and database searches for each species using as much data as could be collected regarding the plant's fire ecology under natural conditions. Searches aimed to be exhaustive and consist of as much data as could be located in 2020. Our machine learning algorithm was trained on 49 species of plants which had their fire risk ranked by 49 managers in Hawai'i in November 2020. The model used a conditional random forest regression algorithm to predict scores for each species using the manager score as the response variable and the fire ecology traits of each plant as the predictor variables to generate a fire risk score. This trained model was then used to predict the fire risk for all species which were not ranked by managers. The model was calibrated such that it is 90% accurate at predicting high fire risk plants and 79% accurate at predicting low fire risk plants. This research and the resulting fire risk model has been published in the journal Biological Invasions by Kevin Faccenda and Curt Daehler (both at the University of Hawai'i at Mānoa).

Note that the analysis doesn't account for a plant species' spatial distribution, population density, or distinct climate and ecosystem conditions (which can also influence fire risk). The fire risk of these species are mostly under "worst case" environmental conditions where the climate is dry enough to maintain fire, but wet enough to allow for plant growth and fuel accumulation. The fire risk ranking should not be taken as a stand-alone risk metric in prioritizing weed control efforts. Rather, this information may also be useful for determining if a newly discovered species poses a potential fire threat in wildland areas.

More general information on the weed risks and ecology of non-native plants in Hawai'i is available from the Hawai'i Invasive Species Committee's Weed Risk Assessment database.
