

# *Kick'n Grass in Hawaii for Wildfire Management & Restoration*

*James Leary Dept. of Natural Resources and Environmental Management  
A presentation for the Pacific Fire Exchange Webinar Series  
November 18, 2018*

## Objective:

Manage grass fuel loads below risk thresholds

## Subjects of interest:

Kikuyu grass (*Pennisetum clandestinum*; *Cenchrus clandestinus*)

Fountain grass (*Pennisetum setaceum*; *Cenchrus setaceus*)

## Learning outcomes from research and experience:

- Residual herbicide activities on dormant fountain grass
- Suppressing kikuyu grass pre- and post-plant herbicide
- Accelerating the restoration trajectory of *Acacia koa*
- Heuristic kikuyu grass growth models

## C<sub>4</sub> grassy biomes

C<sub>4</sub> grassy biomes are dominant in (sub) tropical climatic zones that also support forests

The C<sub>4</sub> photosynthetic pathway differs from C<sub>3</sub> by the addition of a CO<sub>2</sub>-concentrating mechanism at the site of carboxylation; This reduces photorespiration; A competitive advantage of hot, dry environments.

C<sub>4</sub> grassy biomes are hard to predict with global vegetation models based on “Bottom Up” climatic and edaphic conditions (Whittaker 1975)

## Grass Fire Cycle

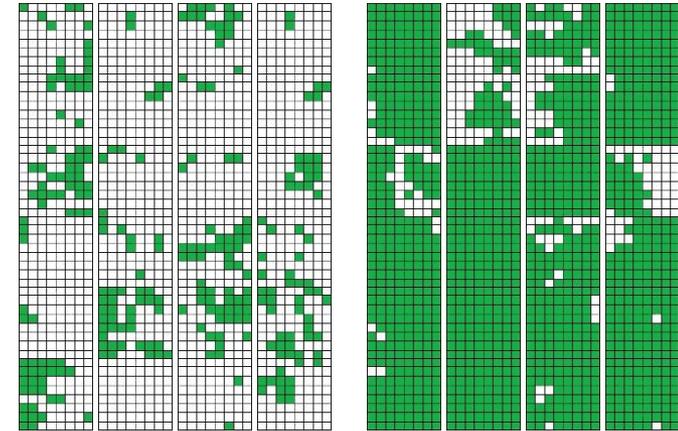

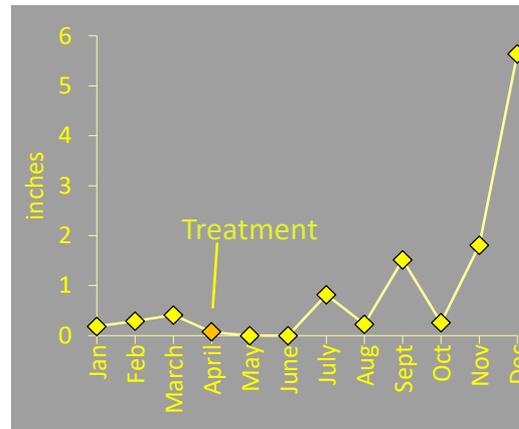

Theoretically, ecosystem physiology should predict woody forest replacement of “early successional” grasslands.

Much of the global mismatch between actual and potential vegetation could be explained by “Top Down” fire (Bond et al. 2005)

The grass-fire cycle is a species driven positive feedback loop perpetuating “Top Down” fire events followed by competitive response advantages exceeding woody species capabilities

# Determine the residual activities of imazapyr and glyphosate on dormant (climax) fountain grass

Approach: Install and monitor a replicated field experiment on dormant fountain grass at Pohakuloa Training Area in 2007

Monthly accumulated precipitation at PTA for 2007 <http://www.met.utah.edu/mesowest/>

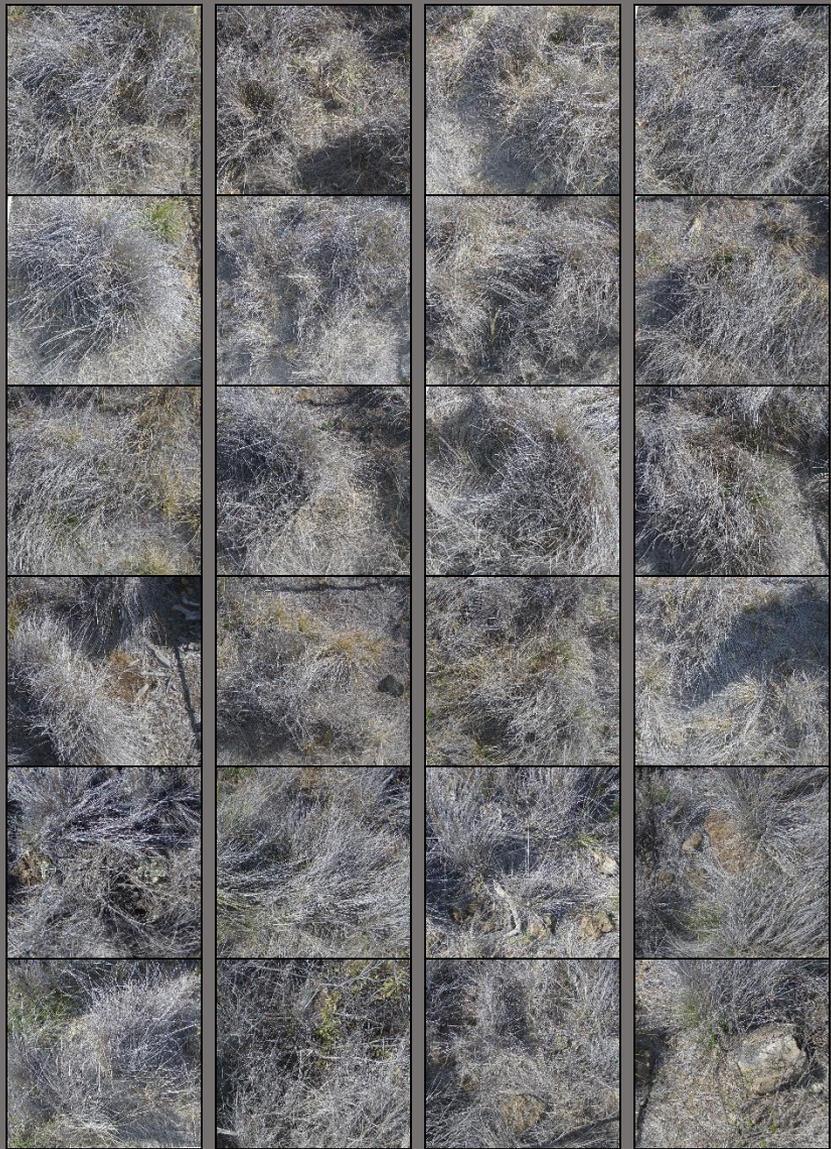

- RCBD replicated 4x; Treatments applied in extreme drought conditions
- Imazapyr (IMZ) applied at  $0.56 \text{ kg a.e. ha}^{-1}$ ; Glyphosate (GLY) applied at  $1.25 \text{ kg a.e. ha}^{-1}$
- with factorial combinations of adjuvants not significantly effective
- Old-school remote sensing with close range nadir images w/  $1 \text{ m}^2$  FOV plot sampling for visual detection of greenness

Symptoms observed January 2008 (41 WAT)

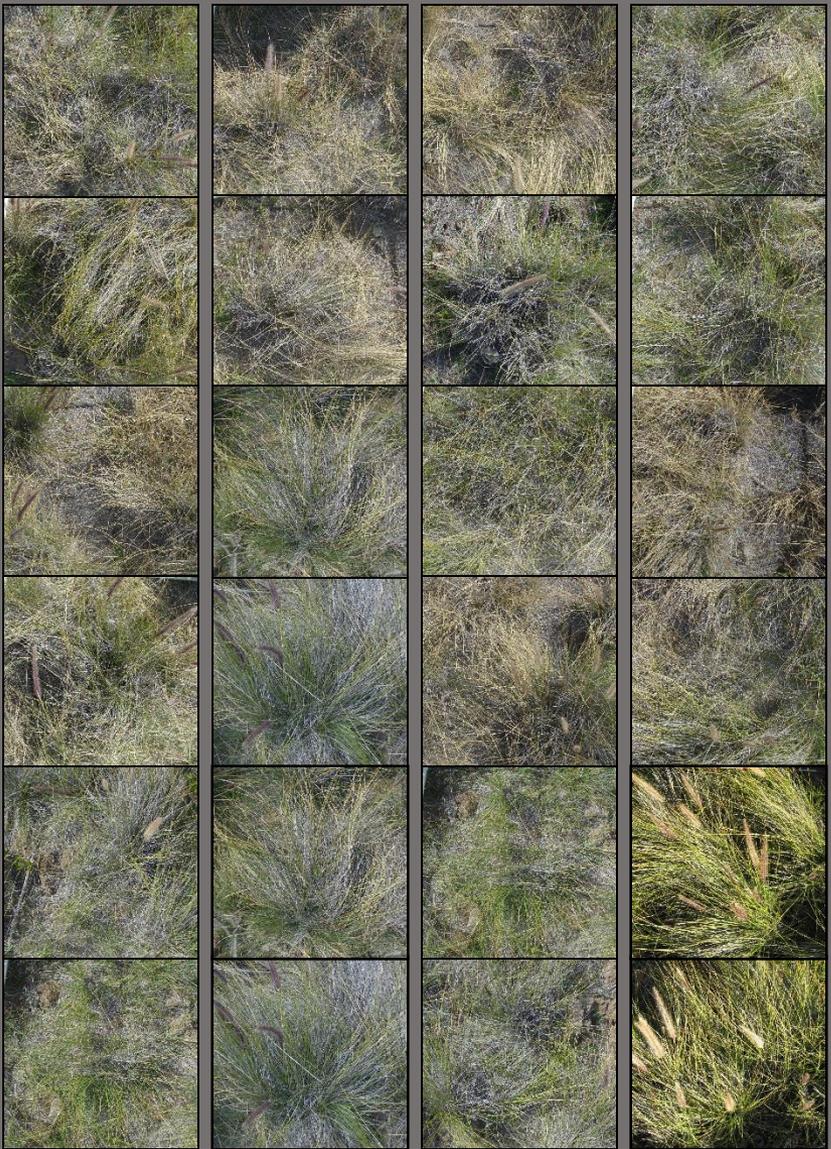

Cropped image data set recorded January 2008 (41 WAT)

imazapyr

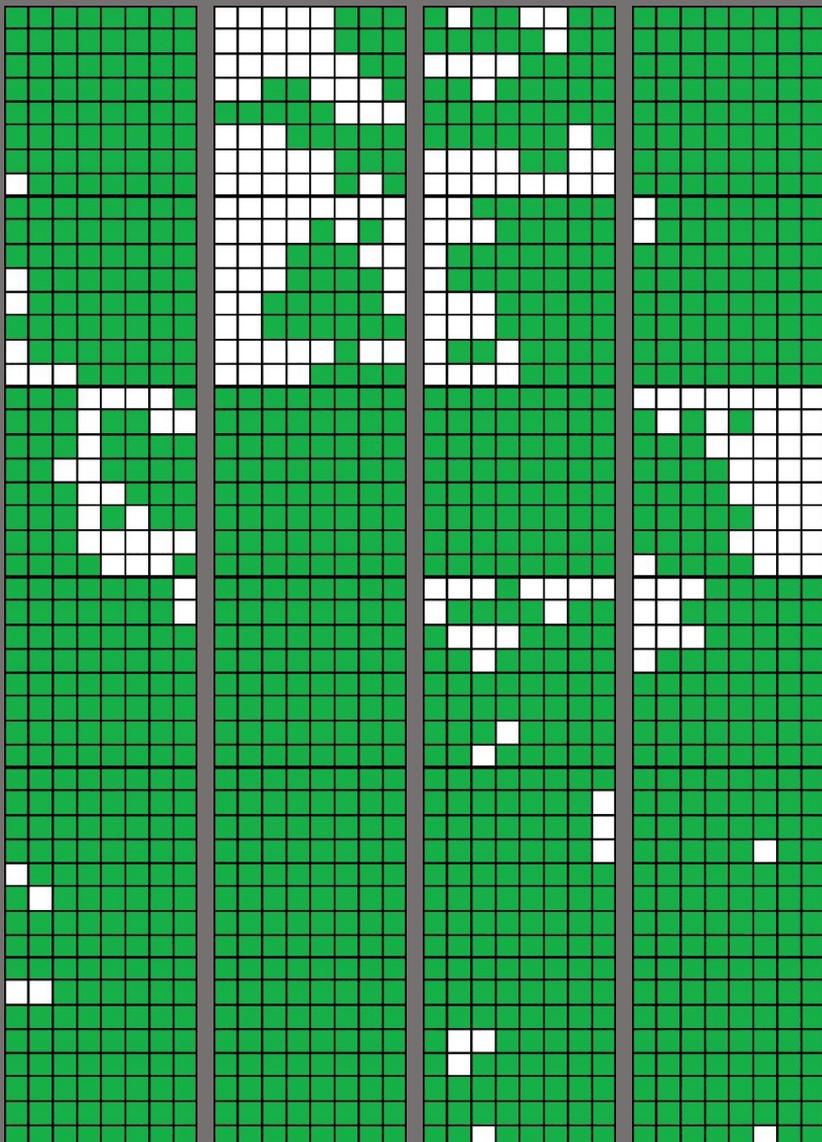

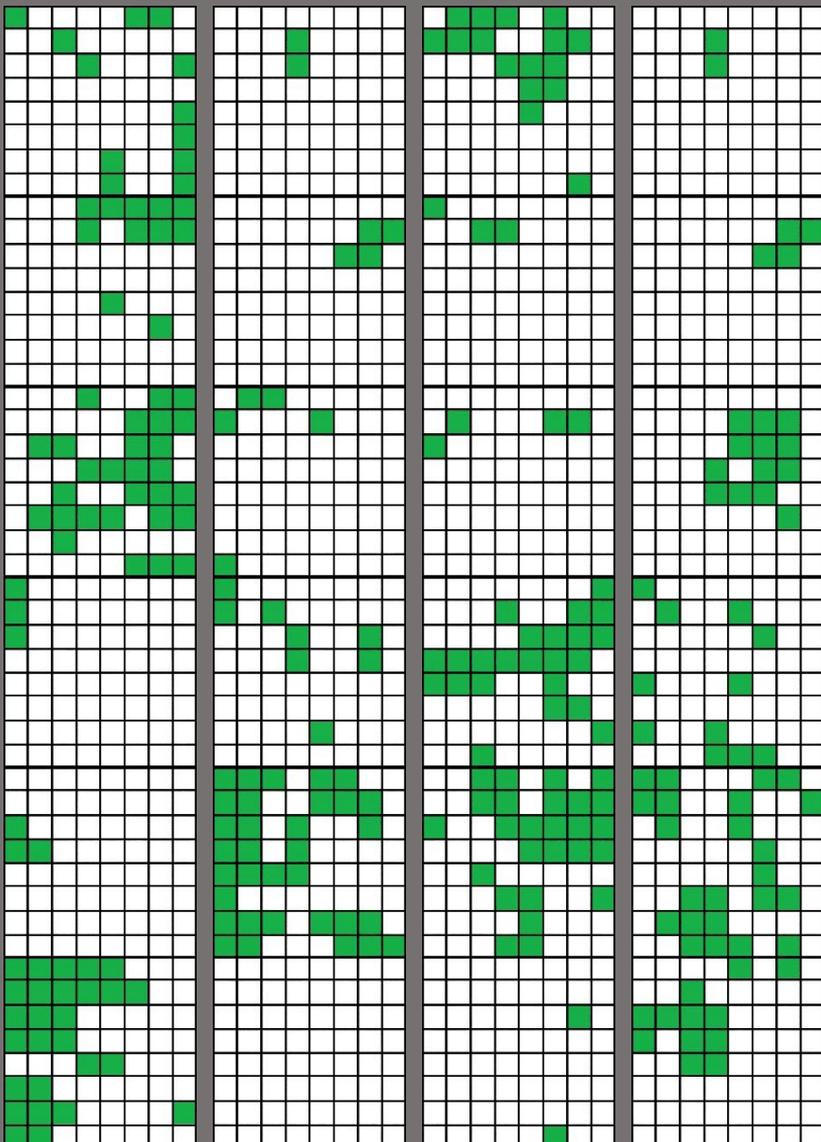

glyphosate

Grid scored by presence (green) or absence (white) of foliage January 2008 (41 WAT)

imazapyr

Regrowth (greening) observed as ramets sprouting from the edge of the perennial clumps

# Determine pre-plant suppression of imazapyr and glyphosate on kikuyu grass, accelerating growth trajectory of outplanted koa

---

Approach: Install and monitor a replicated field experiment at Ulupalakua Ranch, Maui 2011-2013

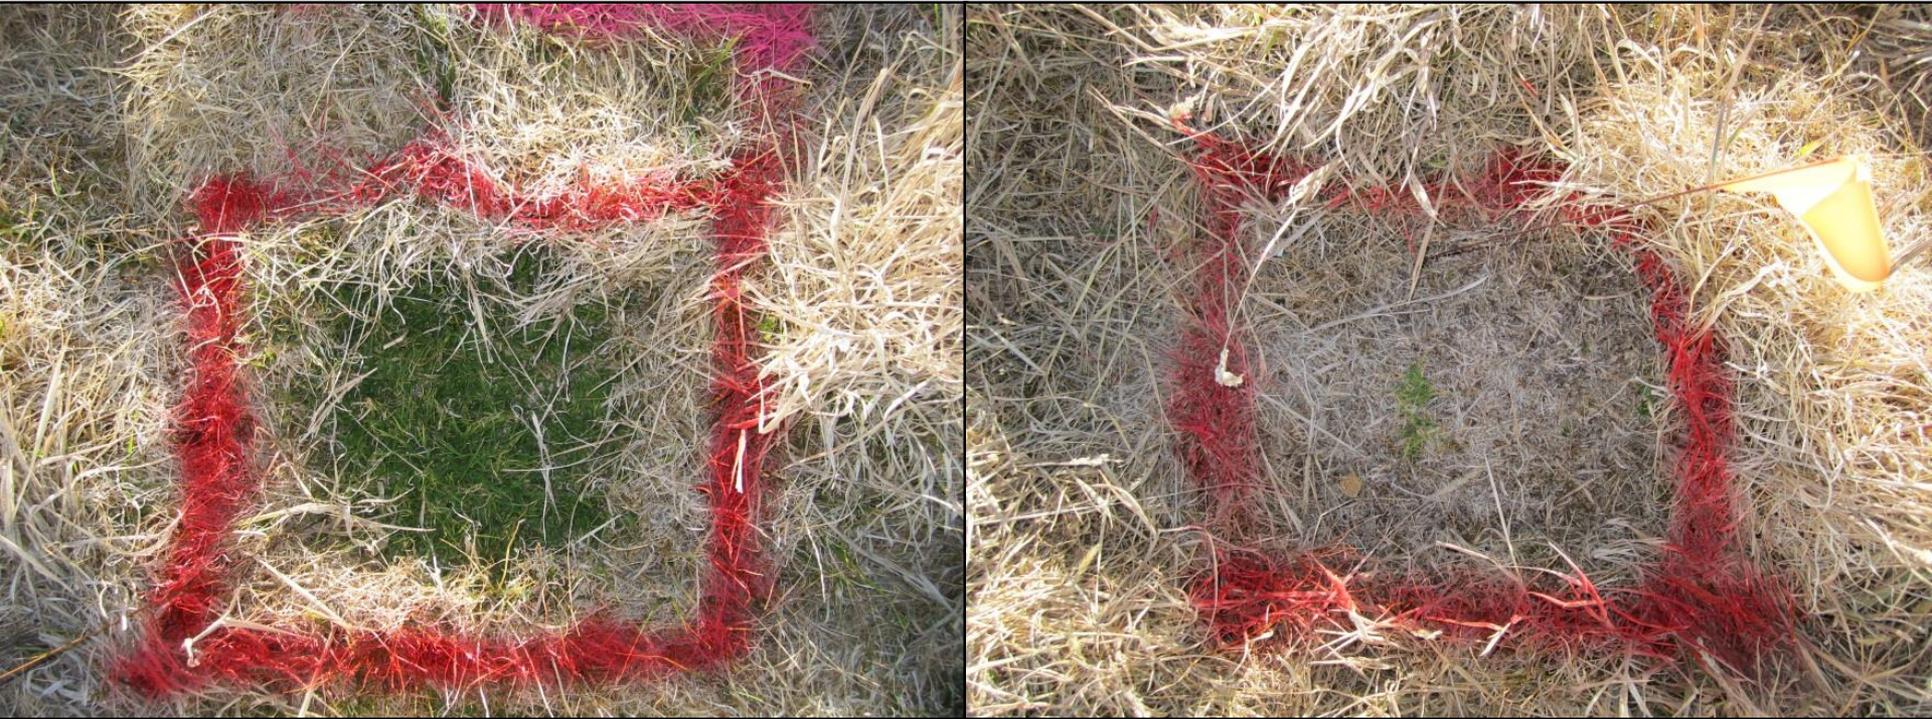

- -1 MAT: on May 2011, herbicide combination of glyphosate and imazapyr applied at  $1.7 \text{ kg ae ha}^{-1}$ , respectively.
- 0 MAT: on June 2011, seedlings ( $\sim 105$  days old) were outplanted in close  $1 \times 1 \text{ m}$  spacing with a total of 20 experimental trees.
- Environmental monitoring with Decagon<sup>®</sup> 5TM soil sensor recording to EM50G data loggers measuring (hourly) T ( $^{\circ}\text{C}$ ) and VWC ( $v_{\text{water}}/v_{\text{soil}}$ )

Ungulate exclusion is a primary step to site restoration, but inherently leads to dominant occupation of the exotic forages.

Kikuyu grass (*Pennisetum clandestinum*) is the most prevalent C<sub>4</sub> species and can produce 15-45 Mg ha<sup>-1</sup> aboveground biomass.

Glyphosate and imazapyr are highly effective short and long-term suppressors of kikuyu grass, respectively.

Glyphosate (left) and imazapyr (right) treatments at 3 MAT. Note how grass is recovering in the clipped area in GLY plot, while IMZ continues to show residual expression.

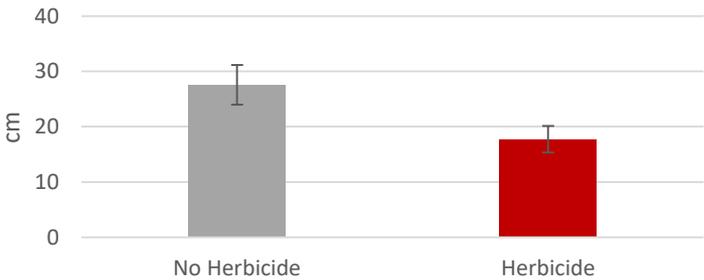

Anecdotal evidence of koa exhibiting imazapyr tolerance.

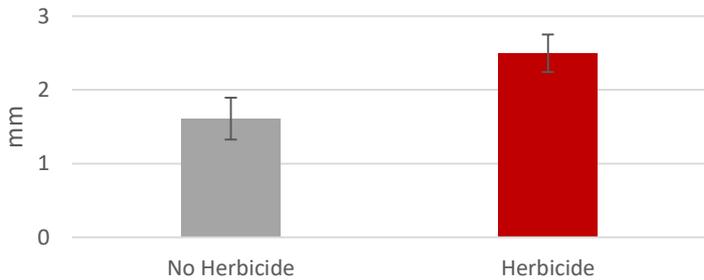

4 MAT: Strong Grass suppression, but also with collateral injury and koa growth suppression exhibited by residual of IMZ application (30 DAT).

Leader ht. (cm)

Root collar (mm)

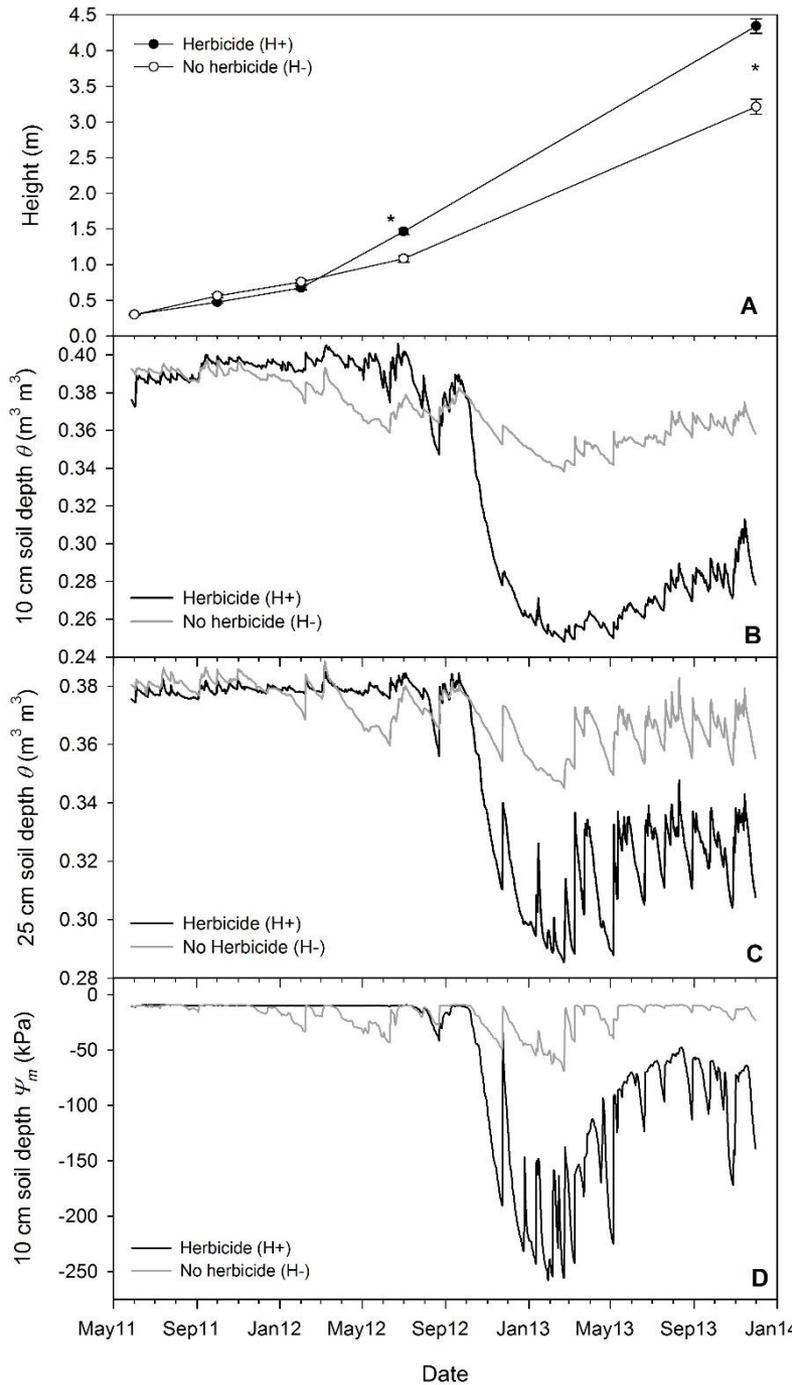

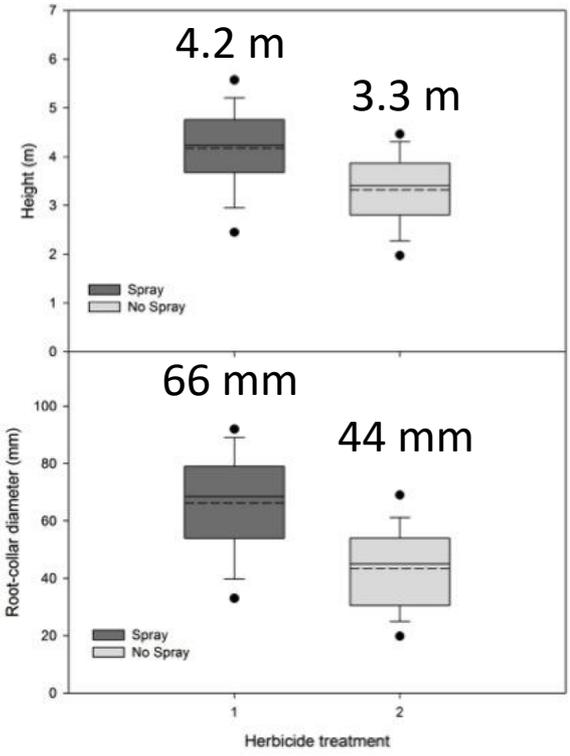

12 MAT: Reversal of fortune with significantly greater koa growth in grass suppression treatment.

>95% survival for the entire experiment!

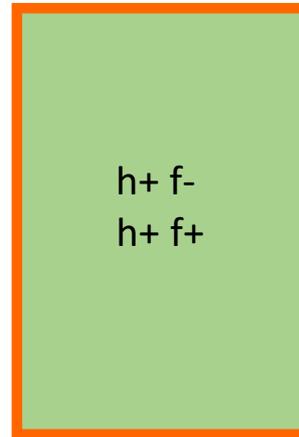

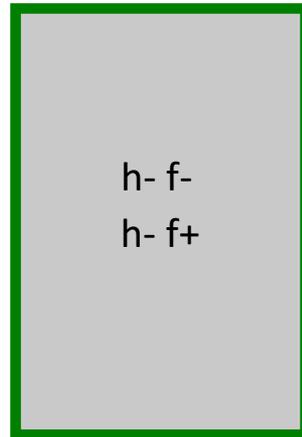

# Results

36 MAT: Drop in VWC corresponding to log-phase growth enhanced by grass suppression.

# Determine Fusilade® DX (a.i. fluazifop-p-butyl) regiment in suppressing kikuyu grass and growth response of Koa

Approach: Install and monitor a replicated field experiments in Humu'ula, Hawaii  
2006-2008

- Treatment design: 2x2 factorial with 5 replications
- Treatments herbicide: fluazifop-p-butyl ( $0.42 \text{ kg a.i. ha}^{-1}$ ); fertilizer: 16-16-16 ( $100 \text{ kg N ha}^{-1}$ )
- Applications made every 4 months for 16 months (total of 4 treatments)
- Monitored aboveground biomass every 4 months (separated into foliar and stolon fractions)

Stolon

Foliar

Thatch

Sward Structure of kikuyu grass consists of three fractions:

- Foliar fraction- the photosynthetic component
- Stolon fraction- the invasive component
- Thatch fraction- the decay component

# Oscillating suppression and recovery of the foliar fraction leading to stolon bank decline

4MA2<sup>nd</sup>

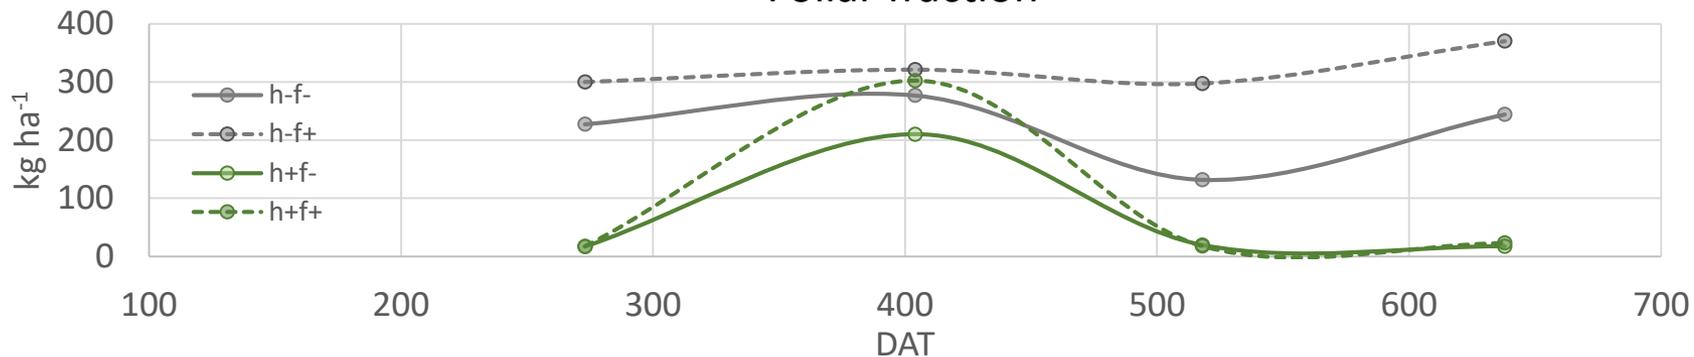

4MA3<sup>rd</sup>

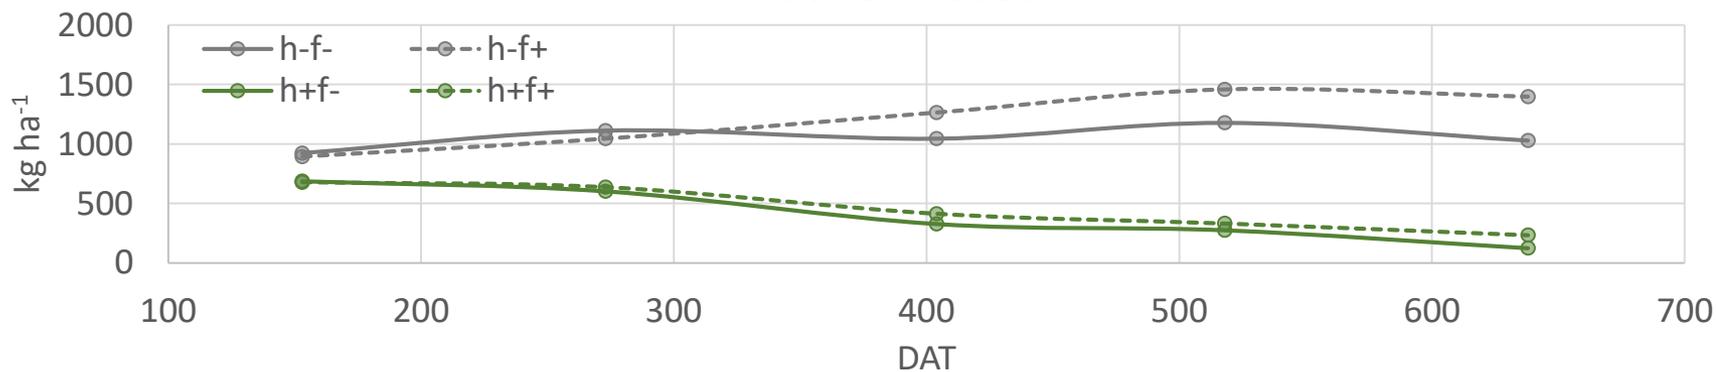

4MA4<sup>th</sup>

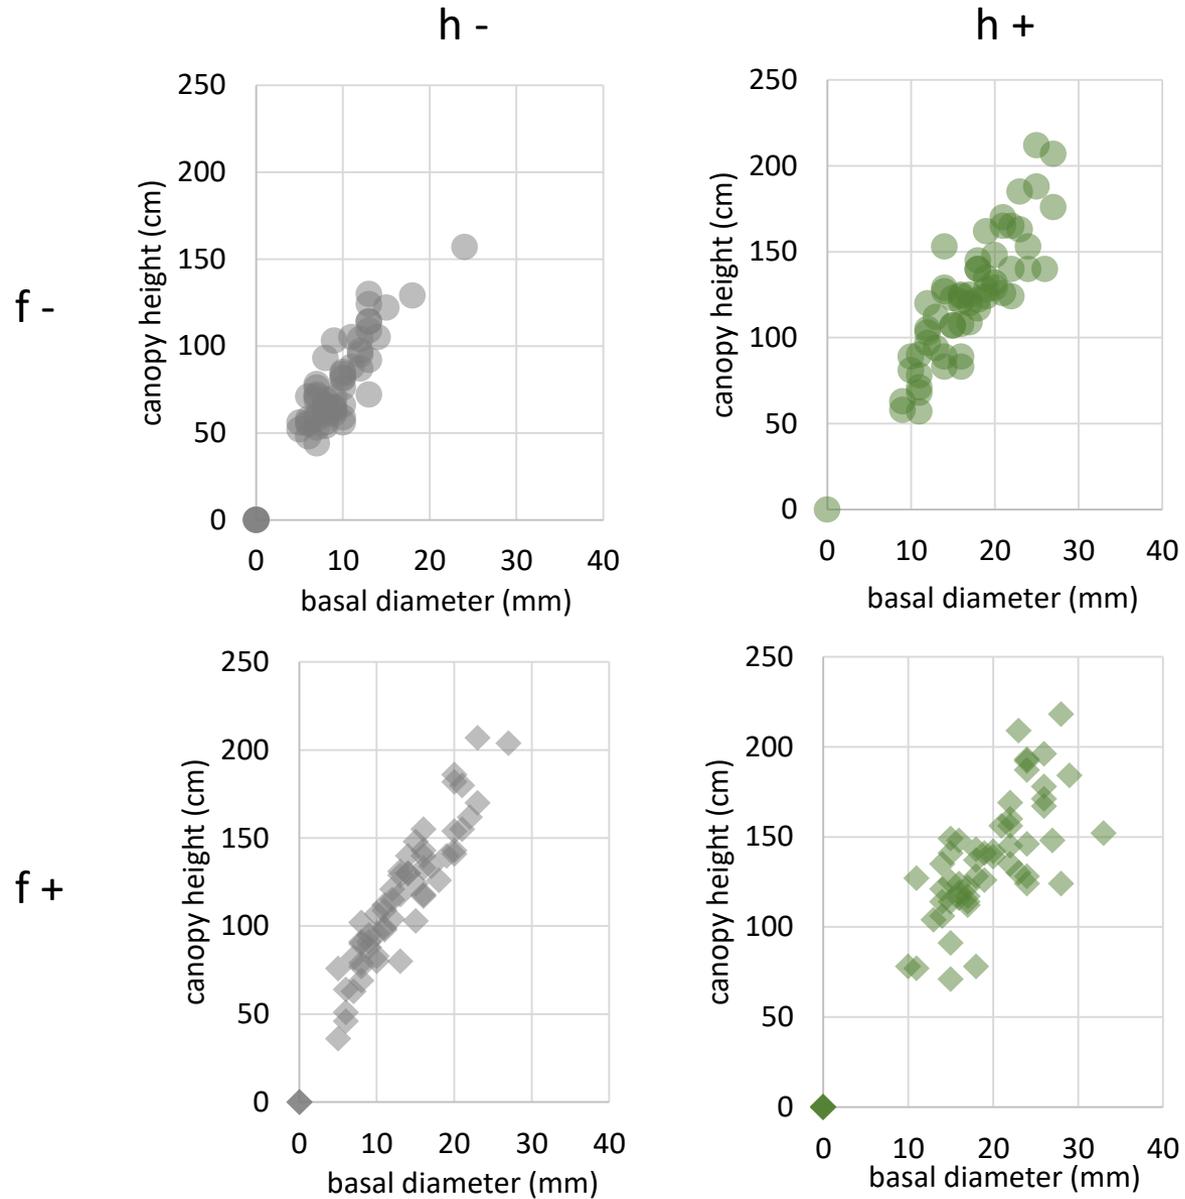

## Foliar fraction

## Stolon fraction

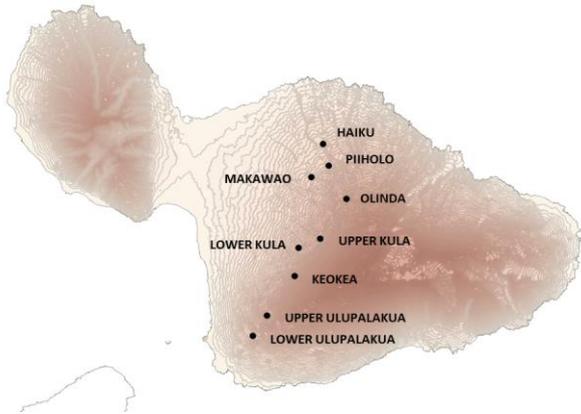

# Herbicide and fertilizer effects on koa growth allometry at 12 months after plant

# Hueristic kikuyu grass growth models in a mesic montane environment for predicting growth responses to climatic conditions

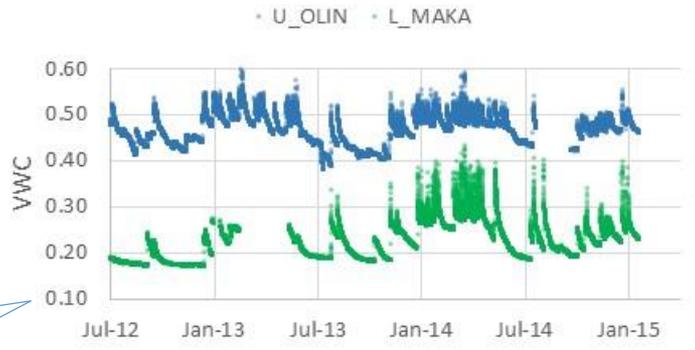

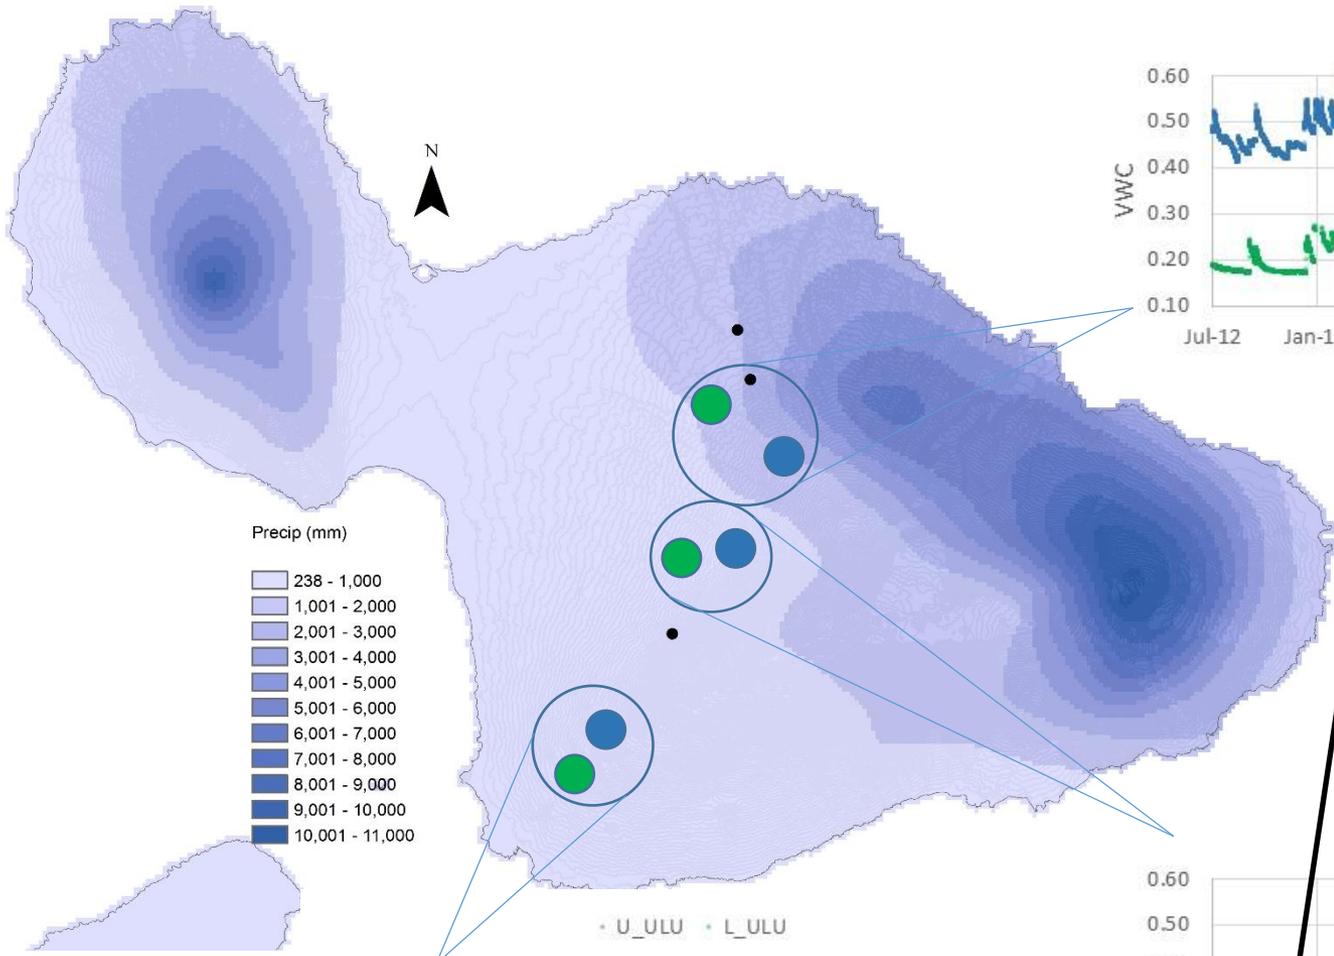

---

Approach: Install and monitor The Kula Belt Pasture Production Observatory Network  
2012-2014

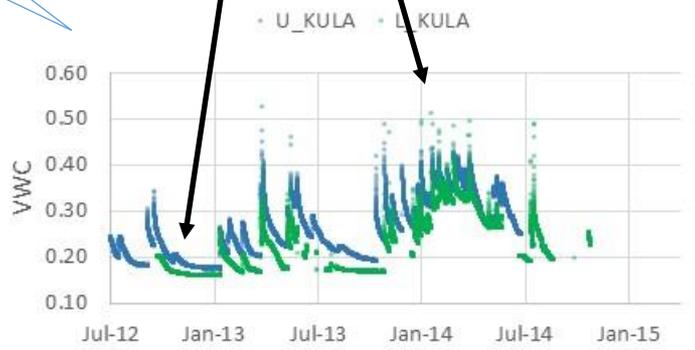

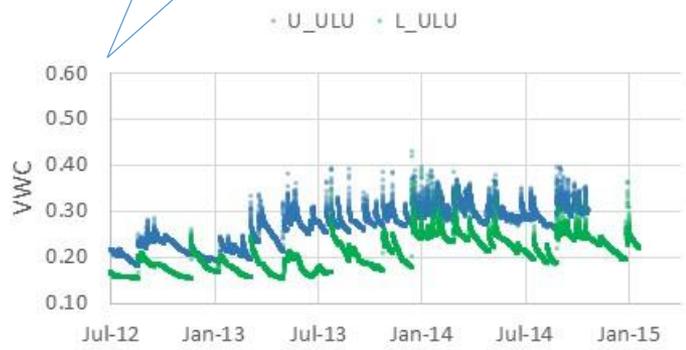

- Nine weather stations installed from Haiku to Ulupalakua, recording PAR, RH,  $T_{amb}$ ,  $T_{soil}$ , and VWC
- Pairs of low (mean 1978 ft. a.s.l) and high (mean 3803 ft. a.s.l) elevation
- Monthly forage samples clipped at 4" (10 cm) stubble height (NRCS recommendation)

# Volumetric Water Content Flux Jul 2012 – Nov 2014

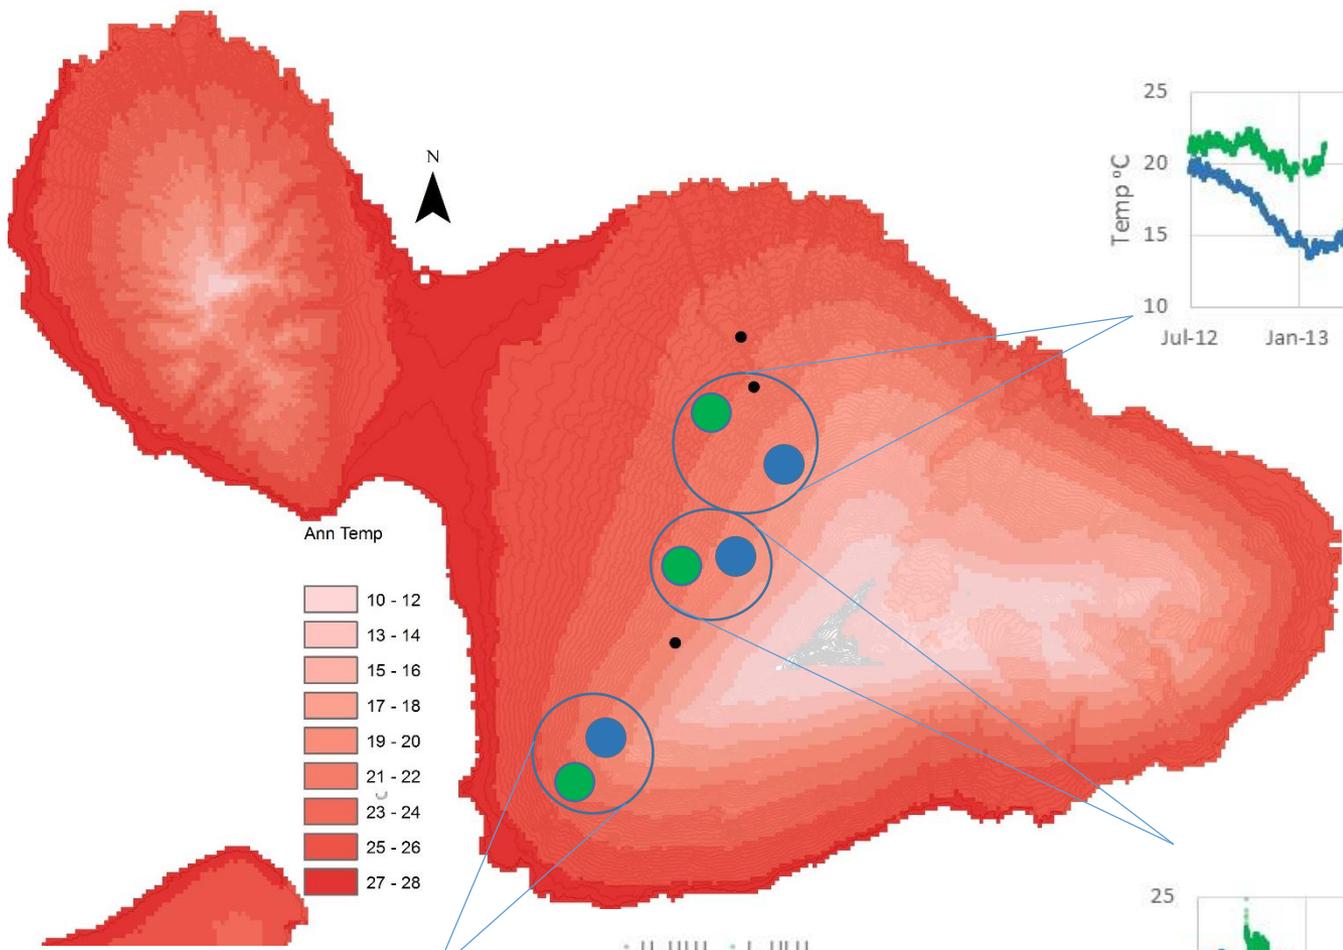

Water content <20%  
WC flatline during  
drought

Recovery with  
frequent precip  
spikes and WC >30%

# Seasonal Soil Temperature Flux Jul 2012 – Nov 2014

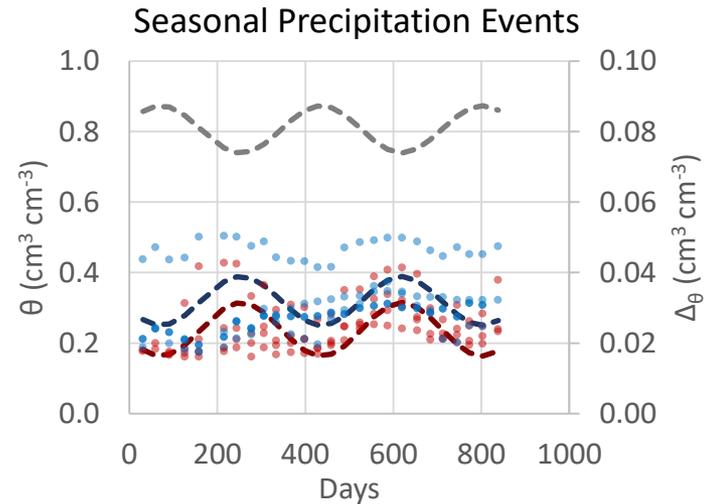

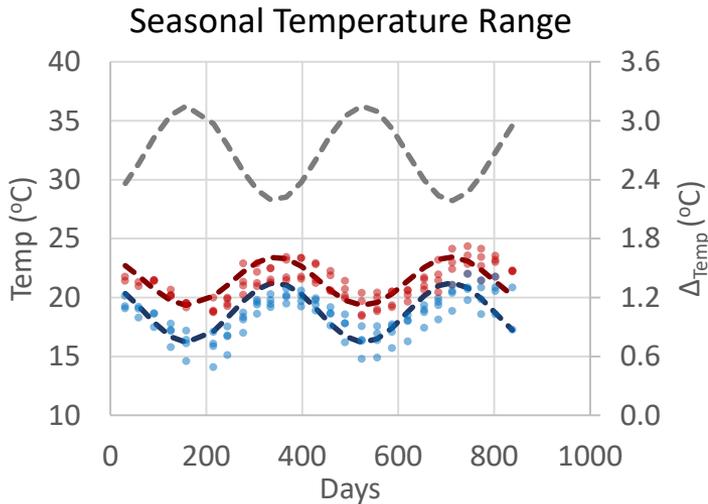

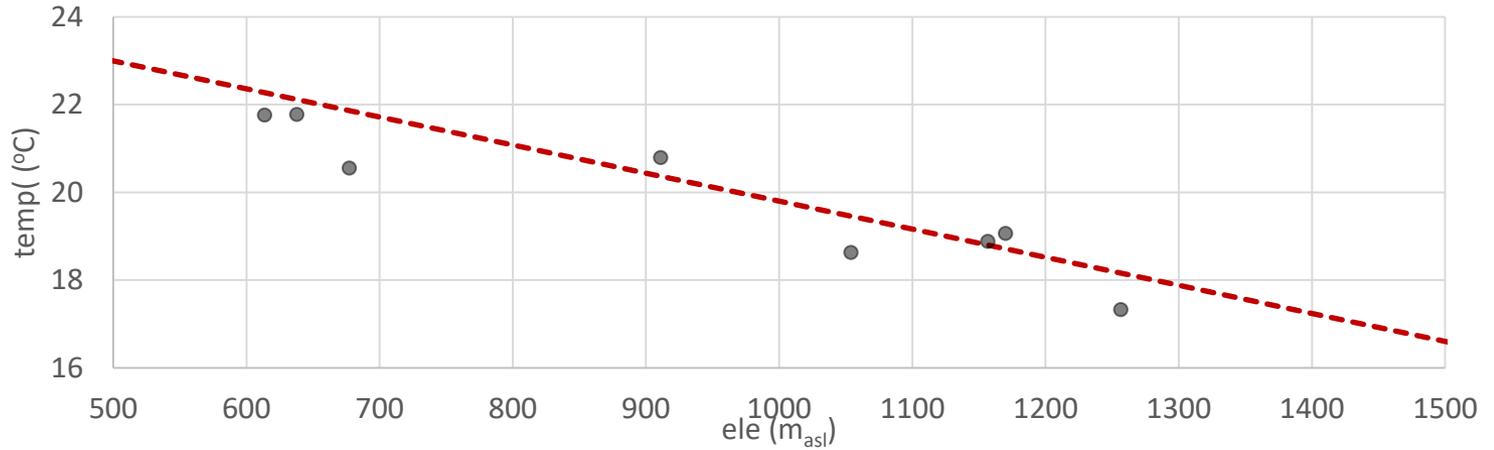

Seasonal T° fluctuation with lower (green) sites always higher by several °C.

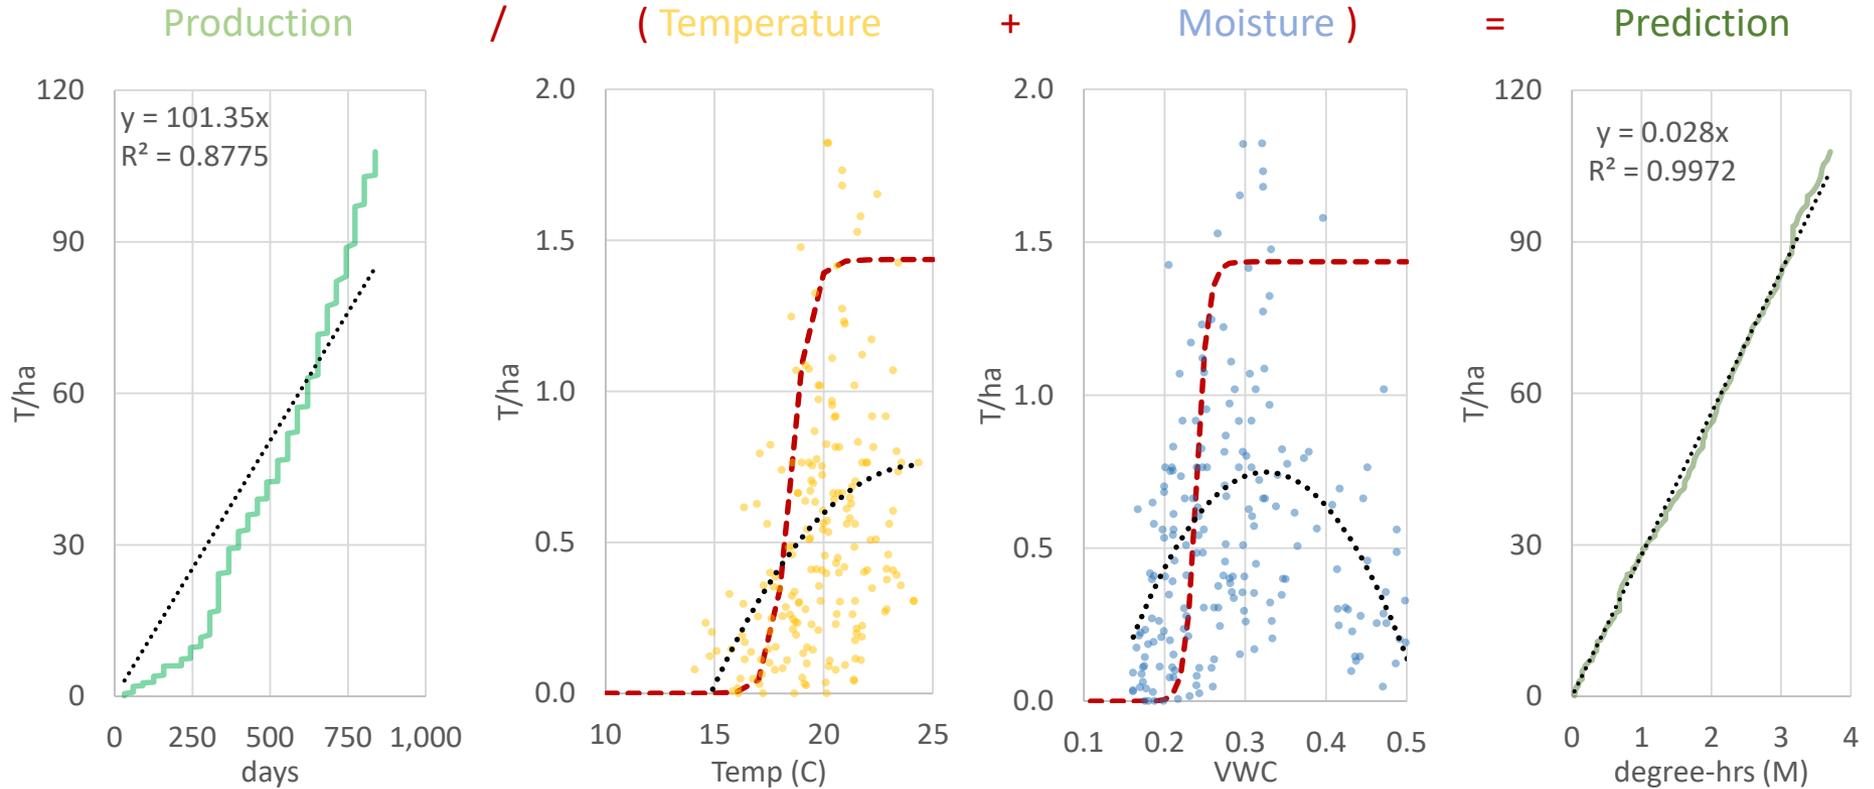

# Trigonometric functions to Model Climate

## Average Environmental Lapse Rate at 6.5° C

# Exploratory research to develop heuristic growth models

Identify optimum and threshold climate parameters with 2<sup>nd</sup> order polynomials and logistic growth functions

Linearize grass production against degree-hours for reliable interpretation as a response to climate

Determine the residual activities of imazapyr and glyphosate on dormant (climax) fountain grass

Conclusion: Imazapyr exhibits residual activity in low moisture conditions offering some flexibility in fuel load reduction, but inferior to timing interventions with green up events, particularly post-fire.

Determine pre- and post-plant suppression of imazapyr, glyphosate and fluazifop-p-butyl on kikuyu grass

Conclusion: These three herbicide options are effective in reducing the regenerative stolon bank and consequently enhances growth performance of outplanted koa overstory.

# Hueristic kikuyu grass growth models in a mesic montane environment for predicting growth responses to climatic conditions

Conclusion: Growing degree-day models could facilitate better monitoring of fuel loading events dictating by elevational and orographic microclimates
